The development of technologically viable electrodes for the electrochemical oxygen evolution reaction (OER) is a major bottleneck in chemical energy conversion. This article describes a facile one-step hydrothermal route to deposit microcrystals of a robust Dexter-Silverton polyoxometalate oxygen evolution catalyst, [Co 6.8 Ni 1.2 W 12 O 42 (OH) 4 (H 2 O) 8], on a commercial nickel foam electrode.

An electrochemical device for oxygen production which makes oxygen on both cathode and anode from air has been developed. The electrolytic cell consists of an air cathode, a catalytic decomposition mesh and a nickel anode. The electrolyser is composed of six single cells. The working surface area of a single cell is 0.02 m². Performance depends on factors such as the basic electrolyte concentration, temperature, air flow rate, gas flow distribution and current density.

Abstract. The development of efficient electrocatalysts for the oxygen evolution reaction (OER) is critical for the generation of renewable energy carrier hydrogen from water splitting. Recently, metal oxides derived from metal nitrides, sulfides, chalcogenides, and phosphides have been demonstrated to exhibit superior catalytic activity as electrocatalysts for the OER but otherwise are difficult to gain access to by conventional metal oxidation methods.

High oxygen reduction (ORR) activity has been for many years considered as the key to many energy applications. Herein, by combining theory and experiment we prepare Pt nanoparticles with optimal size for the efficient ORR in proton-exchange-membrane fuel cells.
